

# Function of the intermediate distribution box

## Overview

The IDF is essentially a local hub or relay station that brings the network closer to users, shortening the distance between devices and the central source of data. This networking component promises to reveal multiple layers of functionality, from basic connectivity. An Integrated Distribution Frame (IDF) is crucial in linking your company's primary network devices to each device, and to allow free passage of data with as few signal losses as possible. Regardless of whether you are building a network for a multi-floor office, factory, or school campus. Business decision-makers evaluating network infrastructure must understand the key differences between Main Distribution Frame (MDF) and Intermediate Distribution Frame (IDF) systems. It acts as a centralized point where incoming data lines from internet service providers or external networks are terminated.
