

Optical Module Return Loss Test Method

Overview

Optical return loss (ORL) measures how much light reflects back in fiber optic systems. Higher ORL values indicate better transmission quality. Use specialized instruments like OTDR and OCWR to check for. To ensure the proper performance of an optical transmission system, various parameters—such as attenuation and optical return loss (ORL)—must be within the acceptable tolerance levels of both the transmission and receiving equipment. ORL is measured according to the characteristics of components. Beginning with software release 1, the reflection above the fiber backscatter level, relative to the source pulse, is called reflectance. As shown in the figures above, the OCWR Testing setup for reflectance or return loss tests of connectors or passive fiber components per industry standards (TIA FOTP-107 or IEC 61300-3-6) using a light source. Reflectance (which has also been called "back reflection" or optical return loss) of a connection is the amount of light that is reflected back up the fiber toward the source by light reflections off the interface of the polished end surface of the mated connectors and air.
